

# NANO VNA-F LOW COST VECTOR NETWORK ANALYZER

DAVE MOORE N7RF

KARS MEETING FEBRUARY 2020

# WHAT DOES A NETWORK ANALYZER MEASURE?

- An **SNA (Scalar Network Analyzer)** measures amplitude only. Example: a VSWR meter is an SNA. Using your radio as a signal source, it measure the amplitude of your transmit signal going to the antenna and the amount of signal reflected back by the antenna.
- A VSWR meter measure  $P_{out}$ ,  $P_{reflected}$  and VSWR. How are there related ?
- The best VSWR is 1:1. This means that 100% of the signal is going to the load (0% reflected)
  - At VSWR 2:1, 11% of the power is reflected
  - At VSWR 3:1, 25% is reflected
  - At VSWR 6:1, 51% is reflected
- As hams, we are always trying to keep VSWR as low as possible to put the greatest amount signal on the air.
- In contrast, a **VNA (Vector Network Analyzer)** is an RF test instrument that measures the amplitude and phase of RF signals. It also computes VSWR but it does a lot more. By adding phase calibration, all measurements have better accuracy.

Table I. VSWR, Reflected Power, and  $\Gamma$  (s11)

| VSWR | $\Gamma$ (s11) | Reflected Power (%) | Reflected Power (dB) |
|------|----------------|---------------------|----------------------|
| 1.0  | 0.000          | 0.00                | -Infinity            |
| 1.5  | 0.200          | 4.0                 | -14.0                |
| 2.0  | 0.333          | 11.1                | -9.55                |
| 2.5  | 0.429          | 18.4                | -7.36                |
| 3.0  | 0.500          | 25.0                | -6.00                |
| 3.5  | 0.556          | 30.9                | -5.10                |
| 4.0  | 0.600          | 36.0                | -4.44                |
| 5.0  | 0.667          | 44.0                | -3.52                |
| 6.0  | 0.714          | 51.0                | -2.92                |
| 7.0  | 0.750          | 56.3                | -2.50                |
| 8.0  | 0.778          | 60.5                | -2.18                |
| 9.0  | 0.800          | 64.0                | -1.94                |
| 10.0 | 0.818          | 66.9                | -1.74                |
| 15.0 | 0.875          | 76.6                | -1.16                |
| 20.0 | 0.905          | 81.9                | -0.87                |
| 50.0 | 0.961          | 92.3                | -0.35                |

# EXPLORE RELATIONSHIP BETWEEN VSWR, RETURN LOSS AND REFLECTION COEFFICIENT

- One of the coolest slide rule calculators one could have before the dawn of desktop PCs and handheld calculators was the Hewlett Packard Reflectometer Calculator. HP sales engineers gave them out as freebies. I still have one dated 1970, and a re-print from Besser Associates dated 2003.
- They are out of print, but there is a virtual version on this web site:  
[http://hpmemoryproject.org/pict/technics/applet/slide\\_rule/reflectometer.htm](http://hpmemoryproject.org/pict/technics/applet/slide_rule/reflectometer.htm) You can use a mouse to slide the top window back and forth and read the scale behind it.

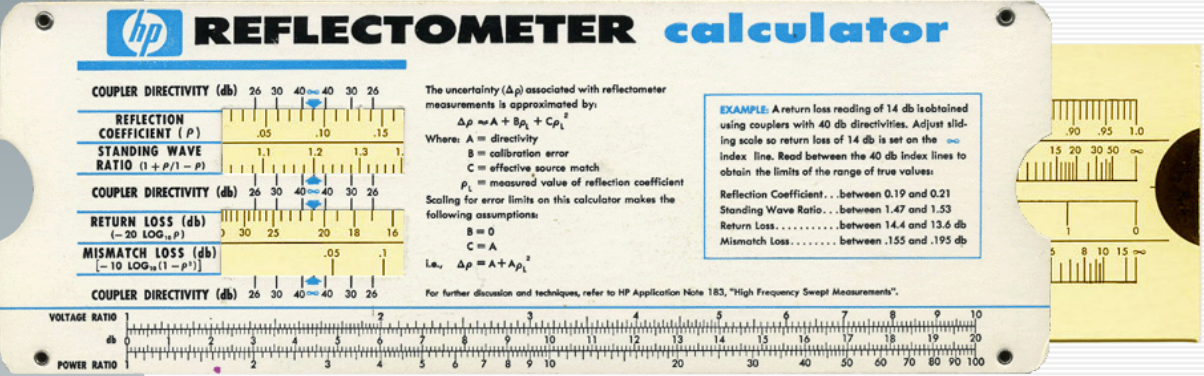

HP Memory Project - Virtual Slide Rule

### HP Reflectometer Calculator

A simulation of the HP Reflectometer Calculator implemented in JavaScript and made possible by the [Walter Zorn library](#).

====> Just click and drag anywhere on the rule <====

hp REFLECTOMETER calculator

COUPLER DIRECTIVITY (db) 26 30 40 30 26

REFLECTION COEFFICIENT ( $\rho$ ) .05 .10 .15

STANDING WAVE RATIO  $(1 + \rho / 1 - \rho)$  1.1 1.2 1.3 1.4

COUPLER DIRECTIVITY (db) 26 30 40 30 26

RETURN LOSS (db)  $(-20 \text{ LOG}_{10} \rho)$  30 25 20 18 16

MISMATCH LOSS (db)  $(-10 \text{ LOG}_{10} (1 - \rho^2))$  .05 .1

COUPLER DIRECTIVITY (db) 26 30 40 30 26

VOLTAGE RATIO

POWER RATIO

The uncertainty ( $\Delta\rho$ ) associated with reflectometer measurements is approximated by:  
 $\Delta\rho \approx A + B\rho_1 + C\rho_1^2$   
Where: A = directivity  
B = calibration error  
C = effective source match  
 $\rho_1$  = measured value of reflection coefficient  
Scaling for error limits on this calculator makes the following assumptions:  
B = 0  
C = A  
I.e.,  $\Delta\rho = A + A\rho_1^2$

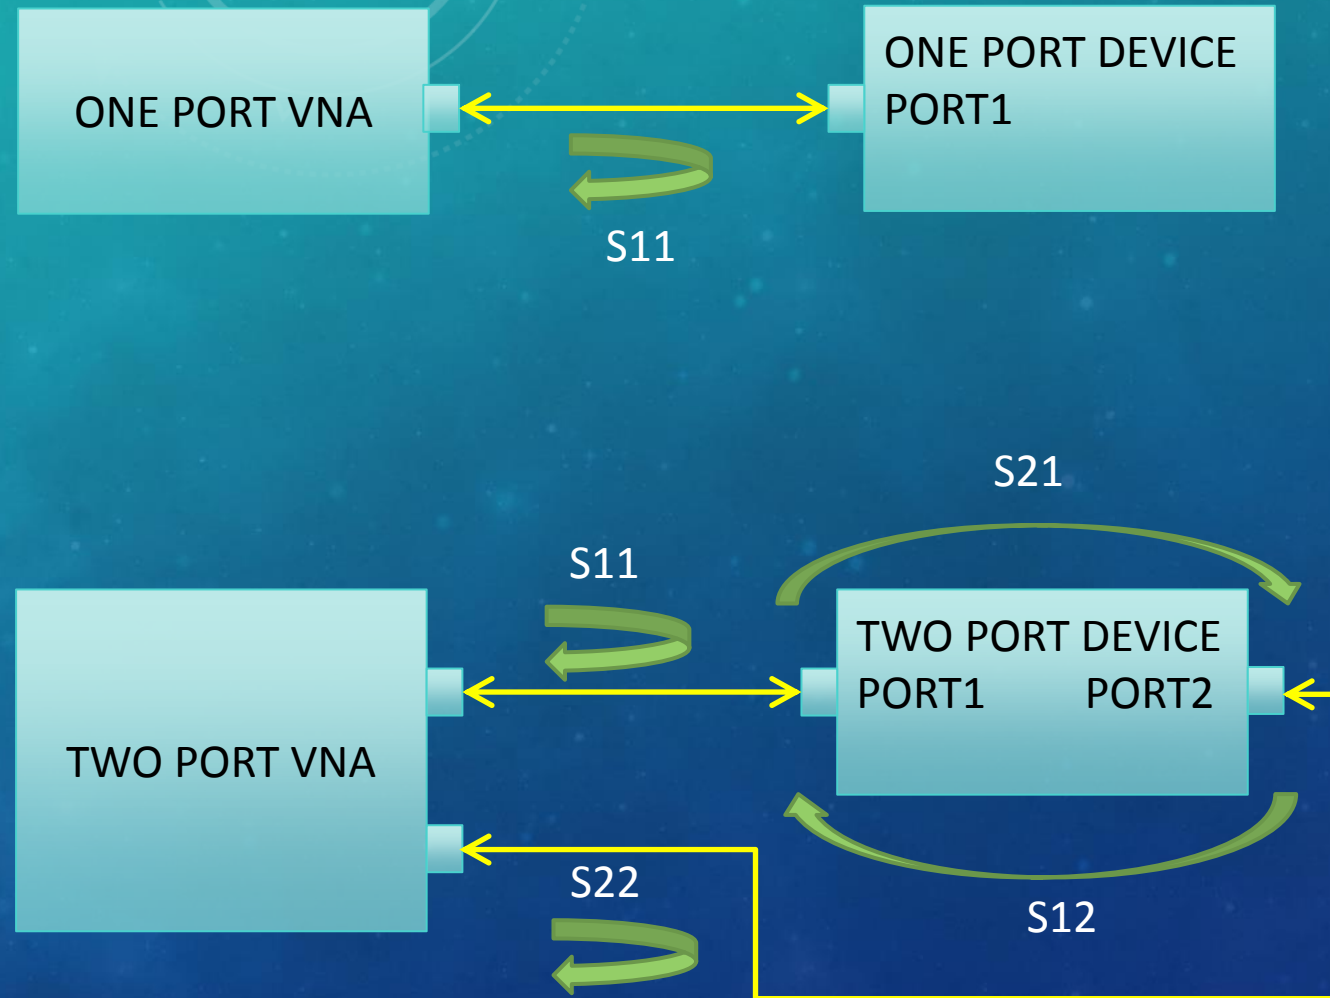

For further discussion and techniques, refer to HP Application Note 183, "High Frequency Swept Measurements".

EXAMPLE: A return loss reading of 14 db is obtained using couplers with 40 db directivities. Adjust sliding scale so return loss of 14 db is set on the 40 db index line. Read the 40 db index lines to obtain the limits of the range of true values:  
Reflection Coefficient . . . between 0.19 and 0.21  
Standing Wave Ratio . . . between 1.47 and 1.53  
Return Loss . . . . . between 14.4 and 13.6 db  
Mismatch Loss . . . . . between .155 and .195 db

# VNA TEST CAPABILITIES

- RF engineers think in terms of **S-parameters**. An S-parameter is simply the complex ratio of one voltage (not power) to another expressed as an magnitude and a phase. From S-parameters, we calculate a variety of other parameters.
- A **one-port VNA** is only capable of measuring  $S_{11}$ , the ratio of the outgoing signal to the reflected signal from the device under test. From that, we calculate VSWR, return loss, mismatch loss, complex impedance  $R+jX$ , cable length, or distance to a cable fault (TDR).
- A **two-port VNA** measures  $S_{11}$ ,  $S_{21}$ ,  $S_{12}$ , and  $S_{22}$ . From the through-port  $S_{21}/S_{22}$  measurements, we get forward and reverse gain or loss in dB, insertion phase in degrees, group delay in nanoseconds, etc.

# COMMERCIAL VNAs

- Commercial VNAs commonly have 2- or 4- ports but are expandable. Custom VNAs can be configured with any number of ports and cover any frequency range up to 220 GHz.

A 4-port VNA measures 16 parameters: S11, S22, S33, S44, S21, S12, S31, S13, S41, S14, S32, S23, S42, S24, S43, S34  
A 20-port VNA, measures 400 parameters!

Keysight PNA Series: (4-port)  
8.5 GHz: \$72,745    13.5 GHz: \$99,500  
26.5 GHz: \$126,780    67 GHz: \$283,333  
110 GHz: \$379,946    120 GHz: \$417,245

+

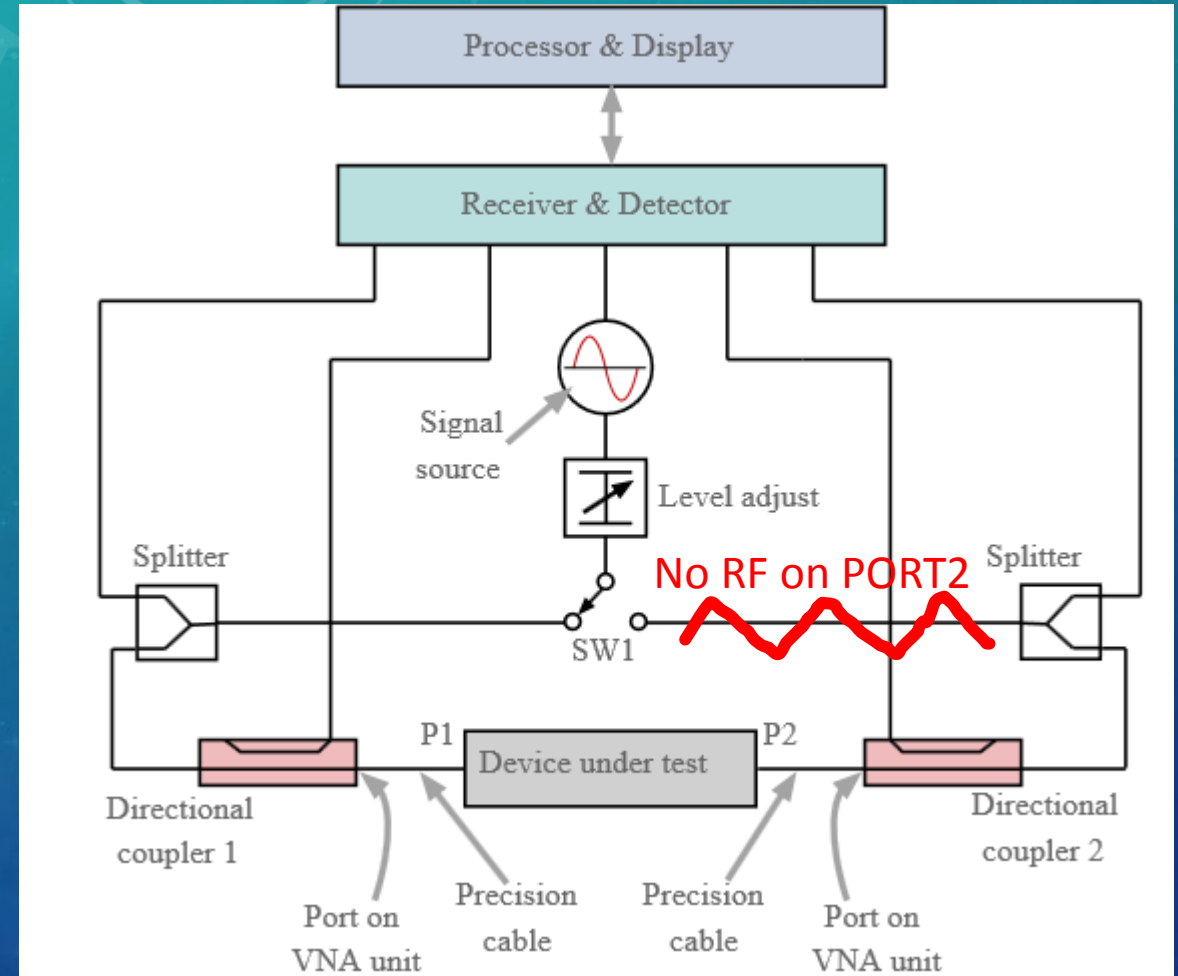

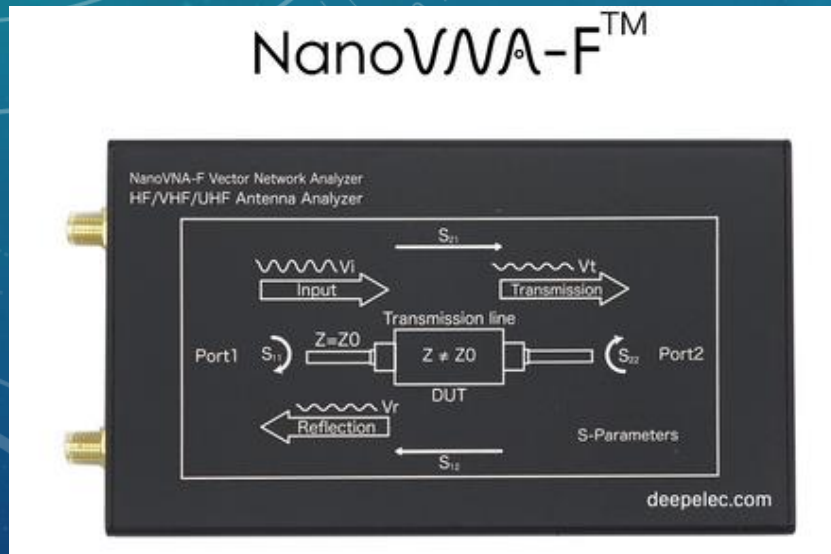

Keysight "Low Cost" SOLT Cal Standard  
18 GHz type N: \$2,914  
26.5 GHz type 3.5mm: \$3,238  
40 GHz type 2.92mm: \$4,050

**\*\$130 is quite a bargain  
for a Nano VNA!**

# HOW DOES A NANOVNA WORK?

- The figure at the right is a typical 2-port VNA. It contains an internal RF source, signal source routing to allow  $S_{11}$ ,  $S_{21}$ ,  $S_{12}$ , and  $S_{22}$  measurements, forward and reflected RF receiver/detectors, processor to do the math, and a graphic display.
- To keep the design low cost, the NanoVNA does not provide an RF signal path to Port 2. Thus it only measures  $S_{11}$  (match), and  $S_{21}$  (gain or loss). However, we can still measure  $S_{22}$  and  $S_{12}$  by simply flipping around the Device Under Test (DUT).

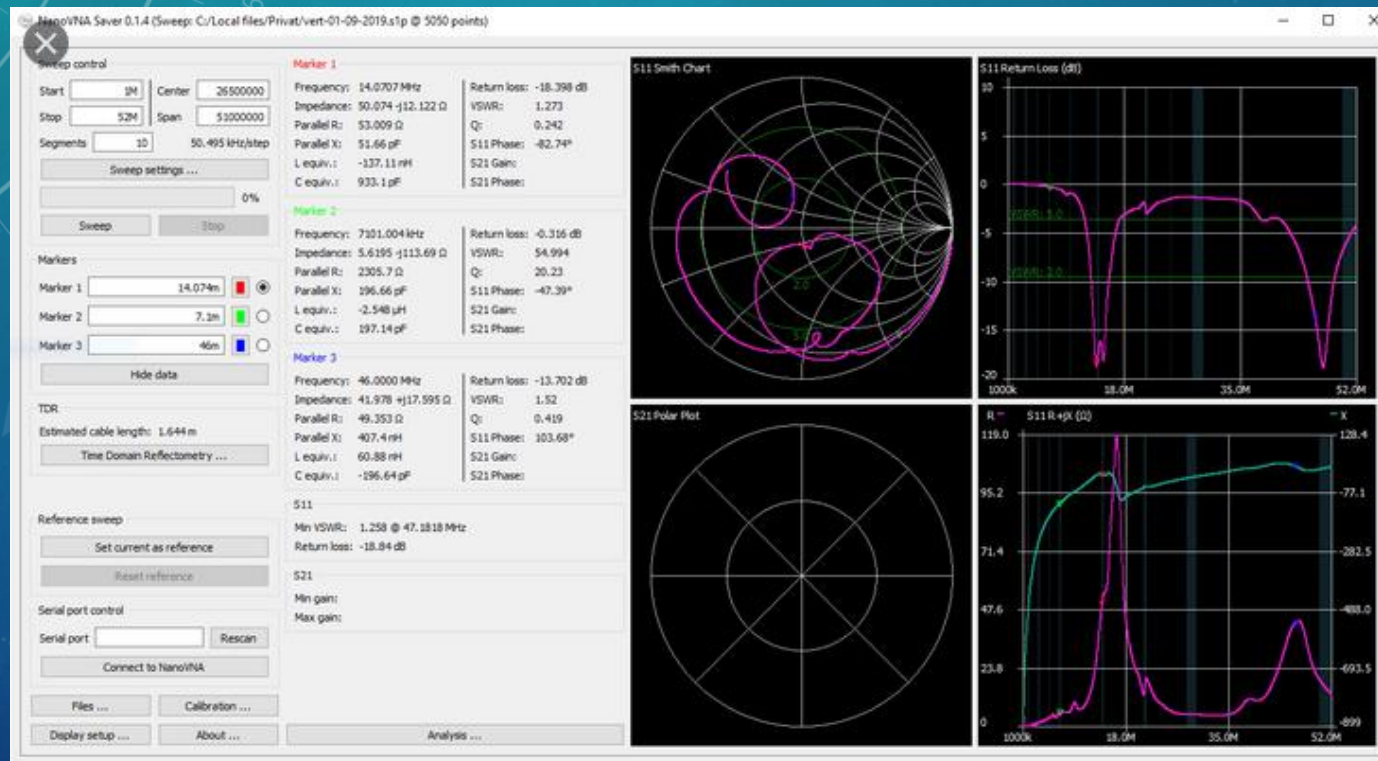

# NANO VNA-F VERSIONS

- Link to purchase at Amazon. May also be available on eBay  
[https://www.amazon.com/gp/product/B0816QXCX1/ref=ppx\\_yo\\_dt\\_b\\_asin\\_title\\_o04\\_s00](https://www.amazon.com/gp/product/B0816QXCX1/ref=ppx_yo_dt_b_asin_title_o04_s00)
- Price on Tuesday was \$130.99. I paid \$139.99 a few weeks ago.
- As sold currently: (1000 MHz coverage): **Version 0.0.4**
- Upgrades on line:
  - **0.0.5**: Extends frequency scan to 1500 MHz
  - **0.1.0**: Fixes minor bugs and adds TDR to measurement list (came out this past weekend)
- I upgraded mine to **0.0.5**, then to **0.1.0**. Upgrading is easy. Method described on groups.io blog page.
  - 0.1.0 version comes up in Chinese, but new menu map on groups.io shows how to fix it
  - <https://groups.io/g/nanovna-f>
- A custom text field can be inserted on VNA start screen (ie, your call letters, etc.)
  - 10 characters in earlier versions
  - 44 characters in version 0.1.0

# NANOVNA SAVER WINDOWS GUI

- Allows data capture in several formats. **Latest version is 0.2.2.**
- GUI requires a certain USB-serial port driver to talk to the VNA using the cable provided. It is an STM32 VirtualComPort driver. It appears to be available online from a number of sources. Thanks to Ben Koerner for installing mine.
- Problems: Window does not scale correctly to monitor settings (wants a really high resolution monitor?); Changing sweep range causes error message “Sweep out of range” for no apparent reason. Axes also do not scale well.

# VNA CALIBRATION

- Remember that a VNA not only measures signal amplitude, but it also measures phase relative to its internal RF source. In order to measure the true impedance or time delay or cable length (etc.) of a test item, we first must establish a phase/amplitude reference plane. This is done with a procedure called an **SOLT calibration** (Short, Open, Load, Through).
- **Procedure:**
  - Set a wide frequency span in the **STIMULUS** menu, say 1-1200 MHz
  - Go to **CAL** menu and connect **OPEN** standard to **Port 1**.
  - Use a stylus to select the **OPEN** tab. The VNA will beep and the tab lettering will invert color to indicate that the cal step is complete.
  - Repeat for **SHORT** and **LOAD** standards.
  - With the **LOAD** still attached to Port 1, press the **ISOLATION** tab
  - Disconnect **LOAD** standard, and connect **short coax jumper** provided between **Port 1** and **Port 2**.
  - Press the **THROUGH** tab. Then press **DONE**. Remove the **short coax jumper**.
- **What happens now?** You have set the measurement reference plane to Port 1. The VNA will measure true complex S-parameters relative to this location.
- **What if it isn't convenient to attach a load directly to the Port 1?** The reference plane can be extended with a length of coax cable. Repeat the CAL procedure by attaching CAL standards to the end of a convenient length cable connected to **Port 1**. The reference plane will then exist at the end of the cable instead of at **Port 1**.
- **Amplitude Only:** if all you care about is VSWR or frequency response then reference phase is not important (amplitude only). You can still calibrate at Port 1, then attach your antenna coax to measure VSWR, or attach a filter with short coax sections and measure response, etc.

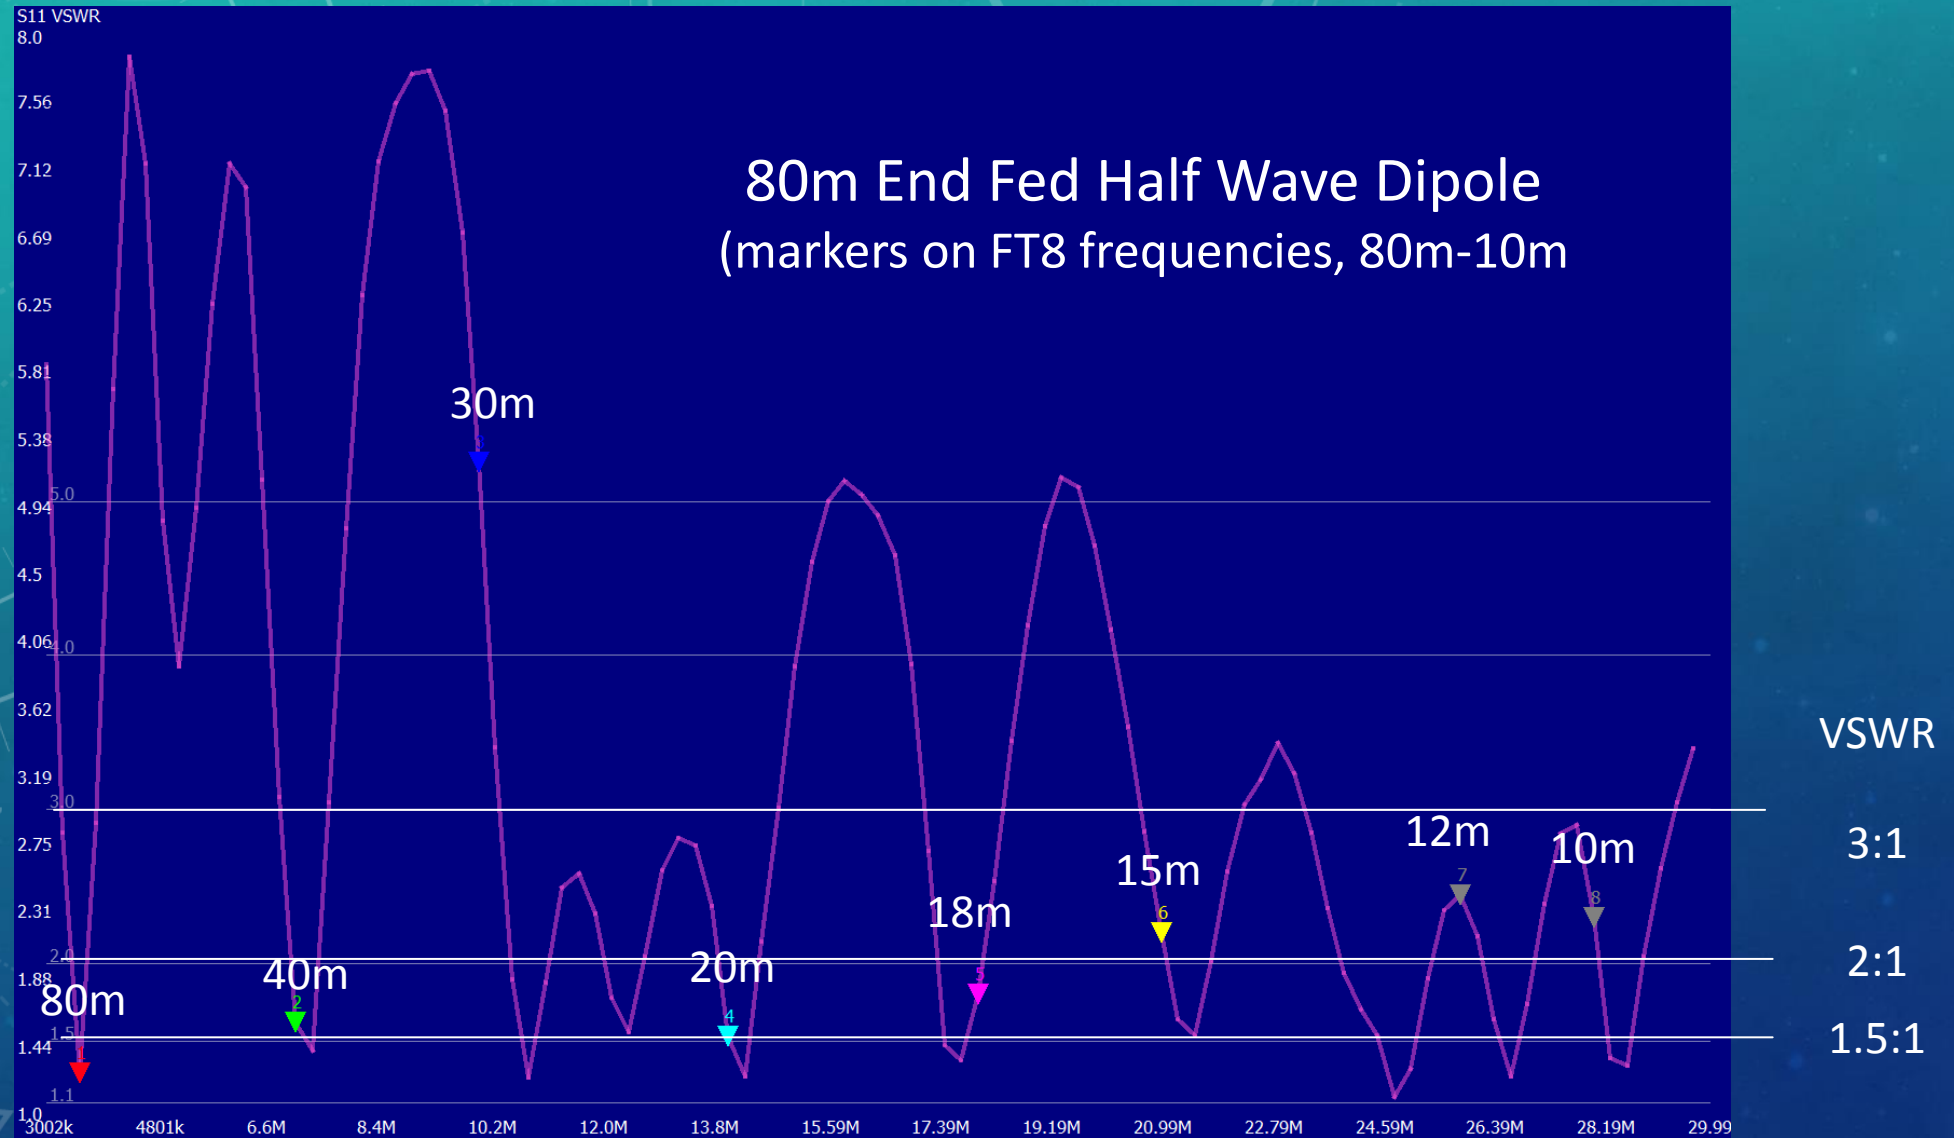

# USES AROUND THE SHACK

- Sweep any ham band up to 1300 MHz.
- One port measurements (**S11**):
  - “Antenna” or other dummy load (VSWR vs frequency)
  - Antennas (VSWR vs frequency)
  - Coax cable length (TDR)
    - Table of standard coax types built in to software!
  - Coax cable distance to fault (TDR)
  - Components (inductance, capacitance, resistance)
  - Home brew RF circuits (impedance matching aid)
  - Tuned circuits/loop antenna (find resonances)
- Two port measurements (**S11, S21**):
  - Bandpass/lowpass/highpass/notch filters (frequency response)
    - Filters for Field Day!
  - Repeater duplexer (insertion loss, isolation)
  - Attenuators (return loss and insertion loss vs frequency)
  - Low power RF amplifiers (gain, reverse gain, return loss vs frequency)
- Signal source – can be set to a single CW RF frequency

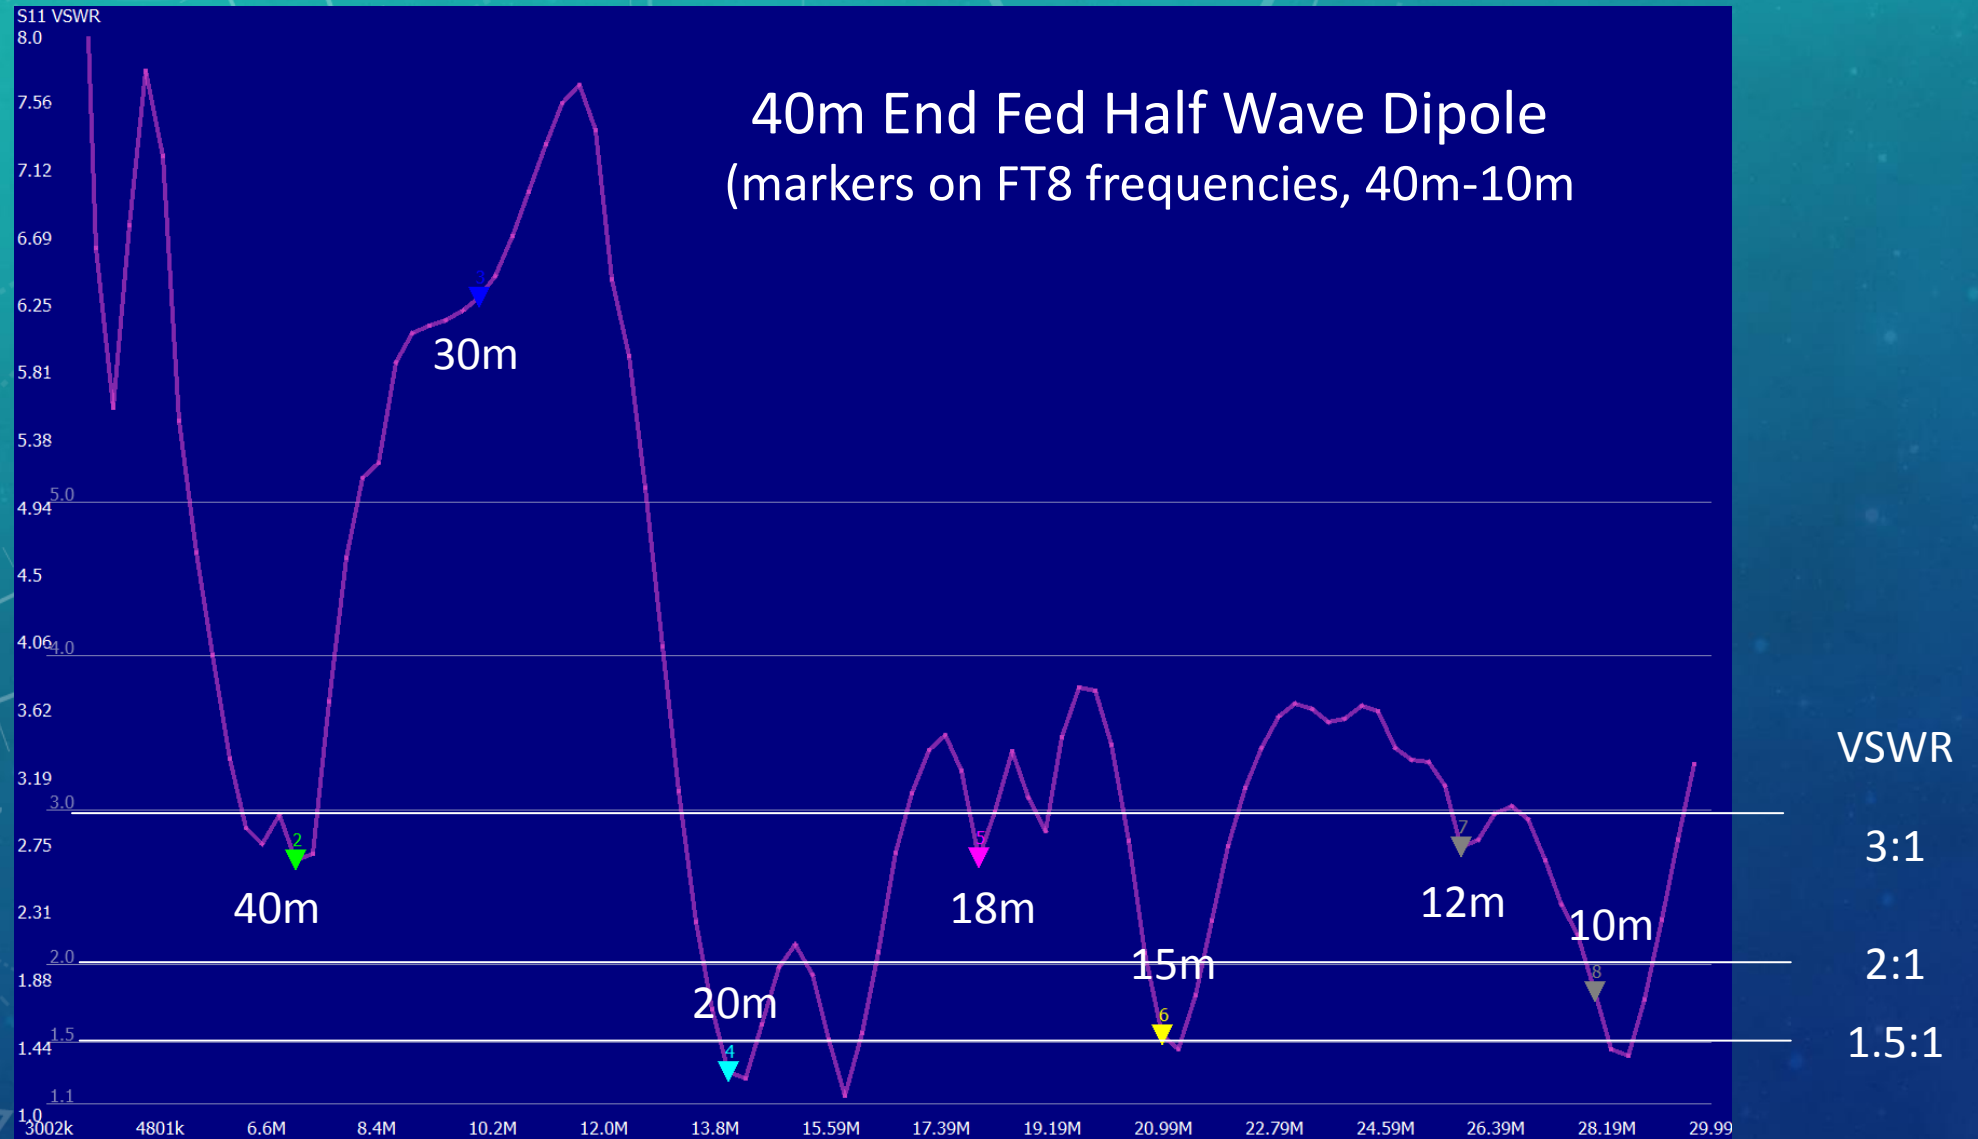

DEMO, FIRMWARE 0.0.5

The background features a dark blue gradient with several semi-transparent white circular gauges and scales. One prominent scale on the left side has numerical markings from 160 to 260 in increments of 10. Other gauges include concentric circles and dashed lines, suggesting a technical or data visualization theme.
